Find all five

In Ep 01 you met five data words: **row, column, ID, data type and messy data**. Here is a table of 40 online orders from August 2026. Open it and find each word yourself, then check your answers on page 2.

No SQL yet? Use Excel or Google Sheets
Open `week1_orders.csv`. Every line is one row.

Have MySQL Workbench?
Open `week1_orders.sql`, run it, and the table is called `orders`.

order_id	customer_id	customer_name	city	order_date	category	amount
1001	17	Ravi Kumar	London	2026-08-03	Electronics	12.99
1002	42	Priya Shah	Leeds	2026-08-05	Books	4.50
1003	58	Ravi Kumar	Leicester	2026-08-09	Clothing	21.50
1004	17	Ravi Kumar	london	2026-08-12	Home	7.99
1005	23	Aisha Khan	Bristol	2026-08-14	Beauty	15.00
1006	31	Tom Hughes	Manchester	2026-08-14	Groceries	3.99
1007	36	Sophie Clarke	London	2026-08-14	Electronics	14.50
1008	45	Arjun Mehta	Birmingham	2026-08-15	Electronics	15.00

The first 8 of 40 rows. Amounts are in pounds (£). The data is made up for practice.

1 Row
How many rows does the table have? What does one row stand for?

2 Column
Name all the columns. Which two would you need to answer "How much did London spend?"

3 ID
Two customers are both called Ravi Kumar. What are their customer IDs, and how many orders did each one place?

4 Data type
For each column, write number, text or date. Which column lets SQL add things up?

5 Messy data
In how many different ways is London typed in the city column? How many orders really came from London?

ANSWERS

Try it first, then check

How did you do?

1 Row

40 rows. One row is one order. So when you count rows, you count orders.

2 Column

7 columns: order_id, customer_id, customer_name, city, order_date, category and amount. For London's spend you only need **city** and **amount**.

3 ID

Customer 17 (London) placed 5 orders and **customer 58** (Leicester) placed 3. Same name, different IDs, so they are two different people. Bonus: there are 12 customers but only 11 different names. Count IDs, never names.

4 Data type

Number: order_id, customer_id, amount. **Text:** customer_name, city, category. **Date:** order_date. The IDs are numbers, but you'd never add them up; **amount** is the one SQL adds up (all 40 orders come to £725.77).

5 Messy data

Four ways: "␣London" · "LONDON" · "London" · "london" (the ␣ stands for a space typed in front). **16 orders** came from London, but only **12** are typed exactly "London". Count only the neat ones and you miss 4 orders. That's why you clean data before you count.

Coming up this week

Ep 02 · Your first query. Same table, first SQL: `SELECT * FROM orders LIMIT 10;`

Ep 03 · Filter with WHERE. Why `WHERE city = 'London'` finds 12 orders, not 16.

Comment **WEEK1** on the reel if a friend needs this file.
