Find all five

In Ep 01 you met five data words: **row, column, ID, data type and messy data**. Here is a table of 40 online orders from August 2026. Open it and find each word yourself, then check your answers on page 2.

No SQL yet? Use Excel or Google Sheets
Open `week1_orders.csv`. Every line is one row.

Have MySQL Workbench?
Open `week1_orders.sql`, run it, and the table is called `orders`.

order_id	customer_id	customer_name	city	order_date	category	amount
1001	17	Priya Sharma	Mumbai	2026-08-03	Electronics	1,299
1002	42	Rahul Verma	Delhi	2026-08-05	Books	499
1003	58	Priya Sharma	Pune	2026-08-09	Clothing	2,150
1004	17	Priya Sharma	mumbai	2026-08-12	Home	799
1005	23	Ananya Iyer	Chennai	2026-08-12	Home	299
1006	31	Arjun Reddy	Hyderabad	2026-08-12	Home	349
1007	36	Sneha Patil	Mumbai	2026-08-13	Electronics	999
1008	45	Karan Mehta	Delhi	2026-08-13	Books	2,150

The first 8 of 40 rows. Amounts are in rupees. The data is made up for practice.

1 Row
How many rows does the table have? What does one row stand for?

2 Column
Name all the columns. Which two would you need to answer “How much did Mumbai spend?”

3 ID
Two customers are both called Priya Sharma. What are their customer IDs, and how many orders did each one place?

4 Data type
For each column, write number, text or date. Which column lets SQL add things up?

5 Messy data
In how many different ways is Mumbai typed in the city column? How many orders really came from Mumbai?

ANSWERS

Try it first, then check

How did you do?

1 Row

40 rows. One row is one order. So when you count rows, you count orders.

2 Column

7 columns: order_id, customer_id, customer_name, city, order_date, category and amount. For Mumbai's spend you only need **city** and **amount**.

3 ID

Customer 17 (Mumbai) placed 5 orders and **customer 58** (Pune) placed 3. Same name, different IDs, so they are two different people. Bonus: there are 12 customers but only 11 different names. Count IDs, never names.

4 Data type

Number: order_id, customer_id, amount. **Text:** customer_name, city, category. **Date:** order_date. The IDs are numbers, but you'd never add them up; **amount** is the one SQL adds up (all 40 orders come to ₹43,112).

5 Messy data

Four ways: "␣Mumbai" · "MUMBAI" · "Mumbai" · "mumbai" (that last symbol is a space typed in front). **13 orders** came from Mumbai, but only **9** are typed exactly "Mumbai". Count only the neat ones and you miss 4 orders. That's why you clean data before you count.

Coming up this week

Ep 02 · Your first query. Same table, first SQL: `SELECT * FROM orders LIMIT 10;`

Ep 03 · Filter with WHERE. Why `WHERE city = 'Mumbai'` finds 9 orders, not 13.

Comment **WEEK1** on the reel if a friend needs this file.
